

Introduction

This document demonstrates multi-column markdown rendering in phppdf. The text flows from the first column into the second column seamlessly as content fills each column top to bottom before advancing to the next.

Features

Column layout supports markdown content including headings, paragraphs, and bullet lists. The cursor advances automatically when a column is full.

- Item one: fast column-aware layout engine
- Item two: automatic page break when all columns are full
- Item three: compatible with all standard

markdown constructs

- Item four: headings rendered in bold at scaled font sizes
- Item five: paragraphs wrap within the column width boundary

Details

Each column receives its own content area derived from the page margins and the gap width. The engine positions the cursor at the top of the next column when the current column overflows, without any caller intervention. Inline emphasis and strong emphasis use the standard 14 font variants.

Conclusion

The multi-column layout works correctly for single-page documents where the total content fits within two columns on a single compact page.
